3. Interrupting the $\mathbf{2 + 2 + 2}$
-there are a number of reactions that start to follow this 2+2+2 pathway, getting to the metallacyclopentdiene or metallacyclopentene, and then go differently
-only a time to look at a couple, but there are many more in synthesis
see: Topics in Organometallic Chemistry 2006, 19 entire issue

## The Pauson-Khand Reaction

-two of the side products from the $\mathbf{2 + 2 + 2}$ are:

(Fe : Knolker, H.J.)
-cyclopentadienones are not very stable compounds, but if one of the $\mathrm{C}=\mathrm{C}$ 's is reduced, you have very useful cyclopentenones
-this type of material is often obtained by using and alkyne, and alkene, and $\mathrm{Co}_{2}(\mathrm{CO})_{6}$ (or an alkyne- $-\mathrm{Co}_{2}(\mathrm{CO})_{6}$ complex)

Intermolecular Cases
-no particular constraints on the alkyne
-if you have an unsymmetrical alkyne, larger groups end up next to $\mathrm{C}=0$, as in

## Alkene Partner

-simple alkenes don't work especially well, unless present in huge excess (Note: this is making progress)
-strained alkenes, "non $\beta$-hydride" alkenes (bridged bicyclic akenes), and alkenes with ligands attached ( $\mathrm{X}=\mathrm{NR}_{2}, \mathrm{SR}, \mathrm{O}$ ? ) give better yield, high regioselectivity

high \%

$\&^{n} \quad \begin{aligned} & \text { even } n=\text { normal } \\ & \text { with mild conditions }\end{aligned}$
especially n = small

"no $\beta-\mathrm{H}^{\prime}$

Cazes (no $\beta-H$ )
Reviews focussing on intermolecular reactions

R Gibson, S.E. et al Angew. Chem. Int. Ed. 2005, 44, 3022. R Laschat, S. Synlett 2005, 2547.
-except for sulphoxides, alkenes with EWG's rarely work

## Intramolecular Cases

-reaction works much better when alkene and alkyne are in the same molecule

-often particularly good for all carbon bridges when there is a gem dialkyl in the bridge

TBDMSO

gem dimethyl or Thorpe-Ingold effect
-there are subtle stereochemical matters which are beyond this course's scope -many recent advances have increased yields and allowed reactions under milder conditions
i.e., polar aprotic solvents $\left(\mathrm{CH}_{3} \mathrm{CN}, \mathrm{DME} \mathrm{MeO}{ }^{\square} \mathrm{OMe}\right)$
-use of $1^{\circ}$ amines $\left(\mathrm{CyNH}_{2}\right)$ and mercaptans ( ${ }^{\mathrm{n} B u S M e)}$
-photolysis
$-3^{\circ}$ amine oxides ( $\mathrm{Me}_{3} \mathrm{~N}^{+}-\mathrm{O}^{-}$, TMANO), (NMO)

R Sugihara Chem, Eur. J. $\underline{\mathbf{2 0 0 1}, ~ 7, ~} 1589$
and room temp

Catalysis
-the new holy Grail - to use catalytic amounts of metal and CO gas (under as low a pressure as possible), or a CO substitute (some aldehydes)

$\xrightarrow[\mathrm{CO}(1 \mathrm{~atm}), \mathrm{DME}\left(60^{\circ}\right)]{\mathrm{CO}_{2}(\mathrm{CO})_{8}(5 \mathrm{~mol} \%)} \quad \mathrm{MeO}_{2} \mathrm{C}$ 83\%
-other metals (other than Co) now are common, especially for catalytic chemistry; I think that $\mathbf{R h}^{1}$ is gradually replacing Co
